

Early Warning Systems: reframing the discussion

Philip Hall proposes a shift in the way emergency managers conceptualise Early Warning Systems

Abstract

In recent years, the focus of the international community in relation to risk, disaster or emergency management has shifted from the development of disaster response capabilities to the need to strengthen risk reduction and control mechanisms and policies, with a particular interest in the design and implementation of better early warning systems as a major mitigator of disasters. The emphasis on early warning systems has turned attention and funding to the current capabilities and developments in science and technology, and unfortunately, distracted us from the central issue of addressing the real needs of the communities and people at risk. This paper argues from a background in mission critical systems, project management and business performance, that we cannot achieve the risk reduction and mitigation we seek until the emphasis is placed on the leadership role of emergency management in providing an effective early warning capability through the integration of the improvements in science and technology with traditional methods and an expanded commitment and involvement by all those at risk.

Introduction

For decades, the international community has discussed and debated how coordinated, collaborative international action can reduce the loss of life, property damage, and social and economic disruption caused by natural disasters. The early emphasis on the development of disaster response capabilities has shifted to the need to strengthen risk reduction and control mechanisms and policies, and most recently, to the design and implementation of better early warning systems. As a result of the International Decade for Natural Disaster Reduction (IDNDR), a rich body of literature now exists on the topic of Early Warning and a variety of successful local initiatives are in place. What has not resulted is coordinated, collaborative international action.

The lack of action is keenly felt within the international community, as is evidenced by the papers presented and workshops held at recent conferences organised around themes such as “Research to Action” (Programme, World Conference on Disaster Reduction, Kobe 2005) and “Concept to Action” (Programme EWCIII, Bonn 2006). While the “Hyogo Framework for Action”, agreed by 168 nations at Kobe, Japan in January 2005, documents international agreement of the need to move from discussion and debate to tangible results, it lacks clear cut and precise goals which would constitute commitments and provide baseline points of reference for participating governments and any subsequent evaluation of achievements. The Framework, however, does specifically emphasise the importance of implementing early warning systems “that are people centered [sic] ... and that support effective operations by disaster managers and other decision makers.” (Hyogo Framework, 17 (ii) (d), p. 9)

Many of us agree on the vision and the importance of translating that vision into a global reality. Why is it, then, that we have not been able to generate a sustainable effort to make Early Warning an international achievement? I believe the answer is that the international community has lost sight of the fact that early warning is the integration and extension of existing emergency management capabilities, and therefore, efforts to establish any local, national, regional and international early warning capability must be led by emergency managers, not by scientists and technologists.

Emergency management is a range of measures that bring together the everyday endeavours of private, voluntary, and government agencies in a comprehensive and coordinated way to deal with the whole spectrum of emergency needs. Through this coordinated effort, emergency managers make use of existing tools and processes, such as weather forecasting, law enforcement, transport infrastructure, health services, scientific modelling, telephony, television and radio broadcasts, and legislation, all of which are used to provide specialised services to the community on a day-to-day basis. In the broadest sense, emergency managers are those who carry out any tasks before, during or after a disaster or emergency, which contribute to enhancing or maintaining the safety of communities from disasters by using whatever tools and processes that are available.

The plans, structures and arrangements coordinated by emergency managers are people-centric, recognising that the community owns the risk and must be given all possible assistance in identifying and dealing with it. (EMA Web Site)

Putting early warning systems into perspective

In 1997, the UN's Guiding Principles for Effective Early Warning stated that the objective of early warning "is to empower individuals and communities, threatened by natural or similar hazards, to act in sufficient time and in an appropriate manner so as to reduce the possibility of personal injury, loss of life, and damage to property or nearby and fragile environments." (Guiding Principles, p. ii) Later that year, the IDNDR Working Group on Early Warning Capabilities summarised years of international debate and expert advice in a report on global experience and current practice on the subject, as well as making recommendations for improvements with particular emphasis on how to ensure that hazard warnings contribute to risk reduction. The result was a thoughtful and detailed discussion of early warning, framed unfortunately in terms of specific systems and sub-systems rather than capabilities (Maskrey et al, 1997).

'Unfortunately' because, despite the fact that few have disputed the validity and importance of the concepts presented in the IDNDR Working Group's report, the international community continues to debate whether early warning systems should involve the creation of effective preparedness and response mechanisms. (EWS Workshop Viewbook, p. 11). I believe that the terminology we are using is causing much of this confusion. A 'system' is generally described as organised or structured, with specific functionality. This description encourages us to think about systems as particular ways of doing specific things, implies scientific and technical leadership, and leads to the kind of questions discussed at the EWS Workshop in Shanghai in 2003. I believe that we would be better able to envision and discuss early warning strategically if it were considered as a capability rather than as a system.

From a strategic viewpoint, an early warning capability is the management integration of expert local knowledge with existing specialised systems and processes, each of which are separately owned and operated by a variety of service providers. Emergency management and its stakeholders assess the functionality and integration of these systems and processes for fitness of purpose relative to a specific hazard, and work with the service providers to extend the functionality or improve the integration of their systems and processes as required toward achieving a more effective and sustainable capability. Without question, an early warning capability provides for preparedness, response, and mitigation mechanisms needed to deal with emergency needs.

Science must provide emergency managers with early notification of a suspected event so that the appropriate levels of response can be initiated

'Early warning system' is an accurate descriptor for the functionality provided by specialised science and technology based systems and processes, such as those focused on the detection and interpretation of hazard events, or issuing alerts and warnings for those events. The science and technology based early warning system, however, is not the primary driver for emergency management processes, although many current discussions of early warning requirements and functionality incorrectly position it in that way.

We can only succeed in meeting the UN's objective for effective early warning if we recognise that emergency management agencies must lead the development and govern the operation of early warning capabilities as an integration of the extensive hierarchy of emergency management services and processes. An effective early warning capability uses the best available science and technology within the all-hazards emergency management approach. To achieve effective risk reduction functionality, emergency management agencies must fully integrate science and technology into, but not allow them to drive, emergency management.

What is early warning?

The word "early" in Early Warning emphasises the need to improve and optimise not only the science and technology, but also the human capability throughout the entire range of interactions that support emergency management. Science and technology must continually improve their ability to accurately detect, interpret, and report a hazard event at the earliest possible moment. The community must, through its vigilance and participation, augment and confirm the information from the scientific or technical systems with local knowledge and observations. Emergency managers also need communications technology infrastructure that

An early warning capability is the management integration of expert local knowledge with existing specialised systems and processes

integrates with traditional methods of communication, so that they can send emergency information out to every community and person at risk.

By reframing the discussion on early warning in terms of the physical issue (i.e. the hazard event), the place of early warning within the context of effective emergency management can be more easily understood. The hazard event is real; everyone, from the international community of experts and specialists to the individuals living in areas that experience the hazard event, can talk about it in tangible terms. Most simply, these tangible terms relate to two operational or functional modes with respect to the hazard event; either:

- Preparing for the hazard event should it occur (i.e. the Prepare State), or
- Dealing with the hazard event when it does occur (including where appropriate as it approaches) (i.e. the Action State).

The hazard event itself triggers our transition from one state to the other; when it occurs, we deal with it and when we have dealt with it, we prepare in case it should occur again.

This proposition, simple and tangible, can be communicated clearly and understood across all possible demographic, gender, cultural, education and livelihood characteristics of the target audiences. It provides a realistic structure within which we can manage the myriad of community awareness, education, scientific, technical, political and logistical details required to prepare for and deal with hazard events. It provides a basic point of reference for emergency managers, planners, politicians, scientists, technologists, and the media; if their actions are not helping prepare for the hazard event should it occur, or helping deal with the hazard event when it does occur, then they are not helping.

Governance of the early warning capability

Reframing the discussion on early warning relative to the hazard event also provides a practical framework for the governance of the early warning capability by emergency managers. Emergency managers govern the early warning capability in accordance with the overall emergency management communications strategy, through which emergency managers agree the terms of and manage relationships with their stakeholders. This strategy identifies appropriate interfaces with the community and with the strategic service providers whose support is crucial if the early warning capability is to be effective – strategic service providers such as scientists, engineers, infrastructure providers, public officials, community emergency services, and the media. Emergency managers must actively lead, engaging their stakeholders in the development of the early warning capability, and strengthen and sustain that capability through a continuous cycle of review, assessment and improvement activities with the community and the strategic service providers.

Effective governance always depends on the unambiguous articulation of roles and responsibilities, and provides for clear prioritisation and delegation. With respect to the early warning capability, I believe it is essential that we clarify and understand the roles and responsibilities of five primary participants: emergency managers, scientists, the media, public officials, and the community.

In the Prepare State, emergency managers function as Project Managers. They are responsible for coordinating the design, development, implementation, and testing of the plans, systems and processes that facilitate the community's capability to deal with specific hazard events.

Science must provide risk information on hazards that may impact the community, and with assistance from the media, communicate that information to the community in meaningful ways. The community has both the right and the responsibility to be informed about risks on which it is expected to have an opinion or to take action. Therefore, the community must actively participate with emergency managers in the development and presentation of hazard preparedness and community education and awareness programs, ensuring that local knowledge and history are included to augment and contextualise the scientific information available.

Emergency managers must collaborate with the community and strategic service providers on the development of hazard preparedness and response plans that take into account such things as what can be done to reduce the potential risks the community faces with respect to a particular hazard; whether and how an early warning can be realistically provided to the community for a given hazard; how notifications relative to a given hazard should be provided to the community for optimal effectiveness; and how both the strengths and weaknesses of traditional knowledge and local resources can be managed to ensure the most effective response.

Science and the community are responsible for maintaining diligent observations and monitoring with respect to hazards. Scientific monitoring systems operate continuously, and science is responsible for maintaining and managing these systems as well as reporting to emergency managers when pre-agreed thresholds have been reached or exceeded. Local observations reported by the community not only assist emergency managers to ground truth the data and interpretations derived from the technology-based systems but in situations such as lahars and local tsunamis, local observations by the community may be the primary or only source of detecting the hazard and raising the alarm.

Responding to alerts and warnings is the responsibility of all stakeholders, led by emergency management. In the Action State, emergency managers act as Operations Managers; they have the immediate relationship with those at risk and the responsibility for activating and managing the response systems established to deal with the hazard event. They are assisted in their decision making by the continual feed of information from science and the community (monitoring and interpretation), and from all stakeholders on the effectiveness of, and their on-going capability to carry out, planned actions.

Under many hazard response plans, science is responsible in the Action State for issuing alerts and warnings to the community through its normal communications channels. In these situations,

the governance model must require that science maintain a close collaborative relationship with emergency managers on the issue of alerts and warnings to facilitate the appropriate community response. Science must also maintain a continuous dialogue with emergency managers about the on-going status of the hazard event and, supported by the media, adhere to the agreed communications strategy for the specific hazard by providing the expected information to target audiences to re-enforce the established hazard response measures. The media, in accordance with the agreed communications strategy, must support emergency managers in the on-going communication with the community, reminding the community of the actions set out in the hazard preparedness plans and informing them of the changing events that guide emergency management decisions on whether to expand or decrease the community's response level. Public officials must activate designated resources and engage with infrastructure providers in accordance with the hazard response plan to support the emergency management measures being initiated.

In governing the early warning capability, emergency managers must take the lead in dealing with two recurring areas of conflict. Scientists often fear that false or inaccurate warnings might result in lack of faith in subsequent warnings and loss of credibility for the scientists. However, even when unable to confirm detection or interpretation, science must provide emergency managers with early notification of a suspected event that may impact the community so that the appropriate levels of response can be initiated. Emergency managers must collaborate with science and the media to inform the community and to establish realistic expectations of the extent and limits of scientific knowledge with respect to the hazards that threaten the community. An informed community, with realistic expectations, can accept false alarms without becoming apathetic or devaluing the professional capabilities of the scientists.

A second area involves public officials who often resist initiating or escalating within the hazard response plan because they are concerned that information and warnings about hazard events will create panic within the community. Rational fear — fear of situations that are liable to occur — generally motivates people to engage in constructive actions to deal with the situation they fear. Emergency managers must collaborate with public officials and the media to provide factual information about the risks the community faces and the options the community has to mitigate and manage those risks. An informed community is unlikely to panic, and adverse economic reactions will be directly related to the hazard event itself.

Conclusion

The international emphasis on early warning systems has shifted the focus, and the funding, from emergency management to science and technology. As a result, scientists and technologists are more and more considered to be leading the development of a global early warning capability. While there are important benefits to be gained from improving our detection and interpretation systems for natural hazards, these benefits will not be realised unless these systems are fully integrated into the all-hazards emergency management capability. Adopting an all-hazards approach, in which local needs are clearly identified and provided for in national and regional policies, generates synergies and efficiencies that can — and must — be leveraged in international strategic planning for early warning capabilities.

To do this, emergency managers need to establish additional, and strengthen existing, international collaboration and exchange of information mechanisms on early warning capabilities just as science has done with early warning system technology. Emergency management must assume the role of ‘Champion’ and actively lead the dialogue at all levels, working with the community and strategic service providers — in particular science, public officials and the media — to develop effective local, national, regional and international early warning capabilities.

Viewbook, *Early Warning System Workshop*, Early Warning Systems Do’s and Don’ts, 20 – 23 October, 2003, Shanghai China: Six years after the IDNDR paper was published, the discussions at the Early Warning Systems Workshop in 2003 illustrate the continuing lack of clarity on what early warning systems actually are or should be. International experts in disaster management and the science that informs it exchanged views on “What is encompassed in a EWS?” and whether a EWS “must involve creating effective preparedness and response mechanisms?” Other questions dealt with at the Workshop demonstrate the participants’ awareness that confusion about the realities of an early warning system extended beyond the experts. The session on Expectations of Early Warning Systems debated “Do we expect too much of an EWS?”, discussed “Hype v. Hope in the use of EWS?” and concluded with an inquiry into whether we should “consider lowering expectations of what EWSs can do for society.” (Viewbook, p. 11)

About the Author

Philip Hall is a Founding Partner of Faerber Hall, a registered consultancy in Australia and the United States. He has extensive experience in delivering operational facilities and mission critical systems in Australia and internationally across a diverse range of applications including scientific facilities and networks. Philip recently coordinated experts across five Australian Government departments to produce the project implementation strategy and plan for the Australian Tsunami Warning System, which was accepted by Prime Minister and Cabinet in July 2005. Currently, he is coordinating national and international partner agencies in implementing the South Pacific Sea Level and Climate Monitoring Project across 12 Pacific Island Countries, a project sponsored by AusAID. Philip was recently appointed as a Member of the inaugural Board of the newly established International Association of Emergency Managers (IAEM) Oceania. He is also a Fellow of the Institution of Engineers Australia.

Faerber Hall focuses on realistic solutions that meet its clients’ strategic needs. Its principal consultants have worked internationally with a wide variety of public and private sector organisations across a broad range of industries. By leveraging the expertise and extensive experience of its principal consultants, Faerber Hall provides clients with a wide array of strategic management services and is able to take advantage quickly of industry standards and best practice to address the unique issues faced by their clients.
